

Next Steps: Backend API Creation

Here is the plan for your backend developer. Their goal is to create an API that the frontend can use to interact with your deployed contract.

1. **Set Up the Project:**
 - Create a new project folder (e.g., `ayur-chain-backend`).
 - Initialize a Node.js project (`npm init -y`).
 - Install the necessary packages: `npm install express ethers`.
2. **Create the Express Server:**
 - Create a `server.js` file.
 - Set up a basic Express server that listens for requests.
3. **Connect to the Blockchain:**
 - In `server.js`, use the **contract address** and the **ABI file** to create a connection to the deployed smart contract using the `ethers.js` library.
4. **Build Two API Endpoints:**
 - **POST /api/herbs:** This endpoint will receive data from the frontend (farmer name, location) and call the `createHerbBatch()` function on your smart contract.
 - **GET /api/herbs/:id:** This endpoint will receive a batch ID and call the `getHerbHistory()` function on the contract to retrieve and return its details.

Once the backend developer has these two endpoints working, the core logic of your project will be complete, and the frontend developer can start connecting to it.
